- Various measures of "aggregate uncertainty" are negatively correlated with economic activity
- Does this correlation reflect causality, and if so, which way?
- The latest VAR evidence suggests a complicated relationship Ludvigson, Ma, Ng (2021):
  - define uncertainty as conditional volatility of forecast errors, aggregated across many series (~Jurado, Ludvigson, Ng, '15)

o distinguish financial from macro uncertainty

- Various measures of "aggregate uncertainty" are negatively correlated with economic activity
- Does this correlation reflect causality, and if so, which way?
- The latest VAR evidence suggests a complicated relationship Ludvigson, Ma, Ng (2021):
  - define uncertainty as conditional volatility of forecast errors, aggregated across many series (~Jurado, Ludvigson, Ng, '15)
  - o distinguish financial from macro uncertainty
  - o financial uncertainty seems to cause declines in production
  - macro uncertainty seems to be endogenous to level shocks and does not appear to cause declines in economic activity

This paper shows very clearly how sizable macro uncertainty arises endogenously in a standard labor search model

This paper shows very clearly how sizable macro uncertainty arises endogenously in a standard labor search model

1. In the DMP model employment is more sensitive to (level) shocks when unemployment is high to begin with

This paper shows very clearly how sizable macro uncertainty arises endogenously in a standard labor search model

- 1. In the DMP model employment is more sensitive to (level) shocks when unemployment is high to begin with
- As a result, employment, and hence output, become less forecastable ⇔ their uncertainty rises
- 3. But this uncertainty has no teeth: a byproduct of slack in the labor market, it cannot, on its own, feed back into output
- 4. Quantitatively, the endogenous mechanism is strong enough to account for 43% of the variance in uncertainty and for the entire correlation between output and real uncertainty
- 5. A recursive identification method that puts uncertainty first erroneously identifies transmission from uncertainty to output

# Discussion

The paper offers a valuable, concrete, thorough contribution My discussion is geared toward where we can go from here I will focus on

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

i will locus off

- 1. The mechanism
- 2. Implications
- 3. Types of uncertainty

• Consider a positive productivity shock in the DMP model.

A higher unemployment state

(a) dampens the increase in the mg cost of hiring  $\Rightarrow$  increases responsiveness of vacancies (and hence emplt) to the shock

$$\mathbf{v}_{t+1} = \left(\frac{\xi}{\kappa}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^{\mathbf{s}} \cdot \lambda_{n,t+1}^{\frac{1}{\phi}}$$

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

• Consider a positive productivity shock in the DMP model.

A higher unemployment state

(a) dampens the increase in the mg cost of hiring  $\Rightarrow$  increases responsiveness of vacancies (and hence emplt) to the shock

$$v_{t+1} = \left(\frac{\xi}{\kappa}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^{s} \cdot \lambda_{n,t+1}^{\frac{1}{\phi}}$$

(b) increases the match rate  $\Rightarrow$  increases sensitivity of employment to vacancies

$$n_{t+1} = (1 - \bar{s}) n_t + \xi \cdot (u_{t+1}^s)^{\phi} \cdot v_{t+1}^{1-\phi}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

• Consider a positive productivity shock in the DMP model.

A higher unemployment state

(a) dampens the increase in the mg cost of hiring  $\Rightarrow$  increases responsiveness of vacancies (and hence emplt) to the shock

$$v_{t+1} = \left(\frac{\xi}{\kappa}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^{s} \cdot \lambda_{n,t+1}^{\frac{1}{\phi}}$$

(b) increases the match rate  $\Rightarrow$  increases sensitivity of employment to vacancies

$$n_{t+1} = (1 - \bar{s}) n_t + \xi \cdot (u_{t+1}^s)^{\phi} \cdot v_{t+1}^{1-\phi}$$

 $\Rightarrow$  Employment is more sensitive to level shocks

$$n_{t+1} = (1 - \bar{s})n_t + \underbrace{\left(\frac{\xi}{\kappa^{1-\phi}}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^s \cdot \lambda_{n,t+1}^{\frac{1-\phi}{\phi}}}_{\text{new matches}}$$

• Higher unemployment state

 $\Rightarrow~$  Employment is more sensitive to level shocks

$$n_{t+1} = (1 - \bar{s})n_t + \left(\frac{\xi}{\kappa^{1-\phi}}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^s \cdot \lambda_{n,t+1}^{\frac{1-\phi}{\phi}}$$

• Higher unemployment state

 $\Rightarrow~$  Employment is more sensitive to level shocks

$$n_{t+1} = (1 - \bar{s})n_t + \left(\frac{\xi}{\kappa^{1-\phi}}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^s \cdot \lambda_{n,t+1}^{\frac{1-\phi}{\phi}}$$

 $\Rightarrow$  Larger forecast errors

$$n_{t+1} - E_t \left[ n_{t+1} \right] = \left( \frac{\xi}{\kappa^{1-\phi}} \right)^{\frac{1}{\phi}} \cdot u_{t+1}^{s} \cdot \left[ \lambda_{n,t+1}^{\frac{1-\phi}{\phi}} - E_t \left( \lambda_{n,t+1}^{\frac{1-\phi}{\phi}} \right) \right]$$

(ロ)、(型)、(E)、(E)、 E) の(()

• Higher unemployment state

 $\Rightarrow$  Employment is more sensitive to level shocks

$$n_{t+1} = (1 - \bar{s})n_t + \left(\frac{\xi}{\kappa^{1-\phi}}\right)^{\frac{1}{\phi}} \cdot u_{t+1}^s \cdot \lambda_{n,t+1}^{\frac{1-\phi}{\phi}}$$

 $\Rightarrow$  Larger forecast errors

$$n_{t+1} - E_t \left[ n_{t+1} \right] = \left( \frac{\zeta}{\kappa^{1-\phi}} \right)^{\frac{1}{\phi}} \cdot u_{t+1}^s \cdot \left[ \lambda_{n,t+1}^{\frac{1-\phi}{\phi}} - E_t \left( \lambda_{n,t+1}^{\frac{1-\phi}{\phi}} \right) \right]$$

⇒ Larger conditional standard deviation – uncertainty – of employment growth

$$\mathcal{S}_t\left[\frac{n_{t+1}}{n_t}\right] = \left(\frac{\xi}{\kappa^{1-\phi}}\right)^{\frac{1}{\phi}} \cdot \left(\frac{u_{t+1}^s}{n_t}\right) \cdot \mathcal{S}_t\left[\lambda_{n,t+1}^{\frac{1-\phi}{\phi}}\right]$$

• One could test this prediction empirically

- The model predicts state-dependence in the response of employment to shocks to the value of a new hire
- One could test this prediction empirically
- One possibility: exploiting cross-sectional heterogeneity
  - For example, high-skill vs. low-skill workers or regional differences in unemployment rates
  - But tricky: structural differences likely affect both long-run unemployment and short-run sensitivity to shocks

- The model predicts state-dependence in the response of employment to shocks to the value of a new hire
- One could test this prediction empirically
- One possibility: exploiting cross-sectional heterogeneity
  - For example, high-skill vs. low-skill workers or regional differences in unemployment rates
  - But tricky: structural differences likely affect both long-run unemployment and short-run sensitivity to shocks
- Another possibility: exploiting aggregate shocks
  - Consider plotting the response of employment to monetary policy shocks in different aggregate unemployment states

 Once you make the link from state-dependence to endogenous uncertainty, it becomes clear that any endogenous variable that has a state-dependent response to exogenous shocks will also have state-dependent uncertainty

• A growing literature empirically documents state-dependence

- A growing literature empirically documents state-dependence
  - consumption response to monetary policy shocks is stronger when mortgage prepayment hazard is high Berger, Milbradt, Tourre, Vavra (2020); Eichenbaum, Rebelo, Wang (2020);

- It may be useful to exclude at least correl(Y, U) from the list of targets, to see what you get from an estimation that does not target it specifically
- Going further, since exogenous uncertainty does not drive economic activity in your model, you could remove the uncertainty shocks from the model and remove all uncertainty-related moments from the targets – again, to report what the "pure" model implies for uncertainty statistics

 The paper shows that a model does not "need" amplification mechanisms from uncertainty to output to match vol(Y), vol(U), or correl(Y,U) – Occam's razor

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ 三 のへぐ

- The paper shows that a model does not "need" amplification mechanisms from uncertainty to output to match vol(Y), vol(U), or correl(Y,U) – Occam's razor
- Nevertheless, I would stress that this lack of amplification is not surprising: there is no mechanism in the model that would allow fluctuations in uncertainty (be it endogenous or exogenous) to amplify output's response to the level shock

- The paper shows that a model does not "need" amplification mechanisms from uncertainty to output to match vol(Y), vol(U), or correl(Y,U) – Occam's razor
- Nevertheless, I would stress that this lack of amplification is not surprising: there is no mechanism in the model that would allow fluctuations in uncertainty (be it endogenous or exogenous) to amplify output's response to the level shock
- Without any such mechanisms, I am not sure the paper provides standalone support for the hypothesis that macro uncertainty fluctuations do not feed into real activity, or for the conclusion that there is little role for policy
- Support for that point rests, in my mind, on the evidence of Ludvigson et al. (2021)

• The paper uses the definition of Jurado, Ludvigson, Ng (2015):

 The paper uses the definition of Jurado, Ludvigson, Ng (2015): uncertainty of a series ≡ conditional volatility of the forecast error that remains after all the predictable variation has been removed:

$$E\left[\left(y_{t+h}-E\left[y_{t+h}|\mathcal{I}_{t}\right]\right)^{2}|\mathcal{I}_{t}\right], h > 1$$

 The paper uses the definition of Jurado, Ludvigson, Ng (2015): uncertainty of a series ≡ conditional volatility of the forecast error that remains after all the predictable variation has been removed:

$$E\left[\left(y_{t+h}-E\left[y_{t+h}|\mathcal{I}_{t}\right]\right)^{2}|\mathcal{I}_{t}
ight]$$
,  $h>1$

 A very sensible definition. But is anyone in the economy making forecasts based on the full *I<sub>t</sub>*?

 The paper uses the definition of Jurado, Ludvigson, Ng (2015): uncertainty of a series ≡ conditional volatility of the forecast error that remains after all the predictable variation has been removed:

$$E\left[\left(y_{t+h}-E\left[y_{t+h}|\mathcal{I}_{t}\right]\right)^{2}|\mathcal{I}_{t}\right], h > 1$$

- A very sensible definition. But is anyone in the economy making forecasts based on the full *I<sub>t</sub>*?
- Consider Bianchi, Ludvigson, Ma (2021):
  - $\circ\,$  use machine learning in data rich environment to construct a machine-efficient forecast ( $\sim\,$  your forecasts)
  - then measure deviations of a variety of subjective forecasts from the machine-efficient forecast

 Consider the estimated common component of biases for SPF and Blue Chip GDP forecasts relative to the machine forecast:

Figure: 5. Bianchi, Ludvigson, Ma (2021)

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

biases are volatile and persistent

 Consider the estimated common component of biases for SPF and Blue Chip GDP forecasts relative to the machine forecast:

Figure: 5. Bianchi, Ludvigson, Ma (2021)

- biases are volatile and persistent
- ⇒ Subjective uncertainty may be more harmful for real activity than a constructed measure of objective uncertainty

# Conclusion

• A very nice paper, both because of the clarity of its analysis and contribution, and also because of the avenues for further research that it opens.
